#### **Huffman Encoding**

- Ciphers substitute one symbol for another
  - Amenable to frequency or pattern analysis
- Codes have an arbitrary meaning
  - Require a key
    - Must be safeguarded and shared
  - "Meet me at Uncle Fred's house on Saturday at 3"
- If you are interested in reading more on codes and ciphers, try:
- http://www.vectorsite.net/ttcode 01.htm

## **Huffman Encoding**

- Useful for data compression
- More frequently used letters get shorter codes
- Less frequently used letters get longer codes

### **Huffman Encoding**

- Cannot be decoded via frequency patterns
  - -Most common letters: E, S, R, N, T
- Word Patterns

**XBC Q WQTJ** 

• In this message, the Q is likely A or I

#### **Huffman Encoding**

- Huffman Encoding is a binary code
- Avoids frequency patterns
- Avoids word patterns

# Huffman Encoding: Example

· Assume a 4 letter alphabet

| <u>Character</u> | <u>Frequency</u> | <u>Code</u> |  |
|------------------|------------------|-------------|--|
| Α                | 3                | 0           |  |
| В                | 1                | 110         |  |
| С                | 2                | 10          |  |
| D                | 1                | 111         |  |

ABABBA is encoded as 011001101100 (12 bits)
Normal ASCII encoding requires 48 bits

## Huffman Encoding: Example

## **Huffman Encoding**

- Additional considerations
- Agree on text source for frequency table
- Always choose 2 least frequent items
- Agree on protocol for Left vs. Right child
   Smaller freq node to left
  - -If tie
    - Use alphabetic  $(\alpha\beta)$  ordering OR
    - Put smaller nodes to left, then  $\alpha\beta$
- BUILD Tree from Bottom UP
